iSCSI allows block access to a target storage device from a host computer on a TCP/IP network. Block access requires that the target storage device support SCSI commands that allow the initiator to send and receive blocks of data to and from the target device. Microsoft iSCSI Software Target Free Download allows you to choose from a wide variety of storage devices that are available for iSCSI. For your convenience, you can customize your target storage device by providing a storage path name that will be used as the path name for the specified target storage device. You can also configure a number of default and custom targets. A configuration file (target.cfg) in the target root directory is automatically used when the target is booted. To specify other configuration options, type the following command: set /target [Target Name] [Parameter Name] [Parameter Value] Use the following table to describe the various parameters for setting the value of a parameter for a target. To reset the parameters to the default values, type the following command: set /target Default_Parameters The parameter name can be any valid string, but it is recommended that you use one of the following parameters when using the /set target parameter command: For more information about the Microsoft iSCSI Software Target, see this article: PROPRIETARY SOFTWARE NOTICE Software features or techniques that are used in the Windows operating system, software or hardware are covered by the applicable U.S. and/or local patents or other intellectual property rights. I have a server which is also my media center. It has 8 disks and 1 DVD drive. All the disks are raided and I want to turn it into storage. I would like to have one storage array that I could put all the virtual machine disks and SQL Server images on. It is a windows server 2003 and I would like to use the iSCSI protocol. What would be the best way to

What's New in the Microsoft ISCSI Software Target?

In Server Manager click New Role. In the Role Services window, select Network Storage (Target) from the list. In the Role Services window, select iSCSI Target. In the Role Services window, click Finish. Type a name for the role (such as iSCSI Target). Select this role from the Server Manager role services tree, or enable the role from the console. Enter a password for the role. Click OK to accept the name. Click OK to create the role. Notes: The iSCSI protocol enables you to store data on networked storage devices. With iSCSI you are able to connect a server to iSCSI-based storage devices over TCP/IP networks, such as IP networks. You must have at least one Microsoft iSCSI Software Target role service enabled on the server to use the iSCSI Target to access iSCSI-based storage. By default, the iSCSI Target role service is enabled on Windows Server 2012 and later operating systems. Restriction: The iSCSI Target role service must be enabled on a Windows Server that runs the Network Services role service. However, this service can be run on any server type, including a Windows Server 2008, Windows Server 2008 R2, or Windows Server 2012. If you want to use a non-Windows Server operating system to run the iSCSI Target role service, you must install the Network Services role service on that operating system. Best Practices: For the best performance, iSCSI Target role services are to be set to Automatic (Automatic (Connection Isolation)) for the following reasons: •Maintains TCP/IP data session connections by automatically detecting connection endpoints and closing open sessions •Prevents a connection conflict between role services •Prevents a multiple connection-per-session limit when a single connection is used by multiple role services •Prevents the use of the iSCSI Target by role services in a storage cluster when the iSCSI Target service is not enabled on any servers in the cluster •Prevents performance degradation by preventing the use of the iSCSI Target service on a remote target when no clients are using the target In Windows Server 2008 and later, the best practice for iSCSI Target role service connection types is Automatic (Automatic (Connection Isolation)). If the configuration is set to Automatic, the server creates a single TCP/IP connection to the iSCSI target for each role service session. When multiple role service sessions access the same iSCSI target at the same time, only one session is allowed on the TCP/IP connection to the iSCSI target. Operation: The iSCSI Target role service is enabled for Windows Server 2008 and later operating systems only. The following information describes how to enable iSCSI Target on a Windows Server 2008, Windows Server 2008 R2, or Windows Server 2012 operating

Some of the things I'm not interested in are specific editions of games (I'm more interested in the codebase), platforms or hardware. If you have any of these things, let me know! I don't consider "Multi-core" systems to be particularly "strong", so let me know if you need multi-cores (you won't be able to play on low-end PCs unless you really need to. I'll be looking at everything at least with a 4core i5 (Quad-Core 4.0GHz) and a 4
